

SYRIA SILICON

Silicon City

Pre-Feasibility Investment Framework · from ~USD 0.55 billion

An advanced-technology manufacturing city on the Al-Qaryatayn silica resource

5 July 2026 · Confidential — for evaluation under confidentiality agreement

1. The vision

Silicon City is a phased industrial complex built on one of the region's largest high-purity silica resources: from mining and beneficiation, through glass and silica-based building materials, to metallurgical-grade silicon, polysilicon in the electronic-grade class (industry standard 9N+, with a technology partner), and solar cell and module manufacturing. It is designed as a sequence of independently bankable phases, each gated on the technical and commercial success of the one before — not a single monolithic bet.

The foundation already exists: a ~100 Mt indicated-equivalent resource with a 99.4% SiO₂ best assay (17 independent ALS Arabia analyses), an operating MoU with the Syrian Ministry of Energy on the basis of mining approval, an in-country operating company, and a 215 km corridor to the Mediterranean port of Tartus with parallel rail.

2. The phases

Phase	Scope	Capex (USD M)	Mature revenue (USD M/yr)	Firm power	Years
A	Mine → wash → leach → high-purity quartz (the USD 105M staged project)	105	35–60	10 MW	0–7
B	Glass manufacturing + silica-based building materials	95–240	60–130	20 MW	3–8
C	Metallurgical-grade silicon smelter, 25–30 ktpa	120–200	45–72	50 MW	5–10
D	Polysilicon, 5–7.5 ktpa (electronic-grade class 9N+ pathway, technology-partner dependent)	80–150	40–75	70 MW	8–12
E	Solar cells and modules, ~1–1.5 GW/yr	150–355	100–180	15 MW	9–13
Power	Enabling infrastructure 100–170 MW firm (hybrid), structurable as an IPP	100–200	—	—	5–12

Core industrial capital (Phases A–E) totals approximately USD 0.55–1.05 billion, with a base planning case near USD 0.65 billion. Enabling power adds USD 0.1–0.2 billion, or can sit with a power partner off balance sheet. Phase A alone is investable today on near-DD-grade numbers; the full city is a decade-scale program.

3. The honest constraint: firm electricity

Everything downstream of Phase B is, at its core, a power project wearing a minerals badge. The smelter requires roughly 45–55 MW of continuous firm power (metallurgical silicon consumes ~11–13 MWh per tonne); polysilicon adds a further 50–90 MW. The Syrian grid cannot supply this today. Phases A and B therefore proceed on modest grid and captive power, while Phases C through E are explicitly gated on a bankable power solution — hybrid solar-plus-storage-plus-thermal, grid rehabilitation, or a dedicated independent power producer. The first workstream an anchor partner should fund is a formal power options study.

4. Estimate class — read this before the numbers

Phase A carries near-due-diligence-grade financials: a bottom-up capital build and a validated financial model exist (available in the USD 105M data room). Phases B through E are AACE Class 5 concept-screening

estimates with an accuracy range of –30% to +50%: they rest on industry benchmarks and the company's national solar-manufacturing file, not on vendor quotes, site engineering, or a completed power study. We present them as ranges deliberately. A framework that admits what it does not yet know is worth more in due diligence than a point figure that cannot be defended.

On product grades: "9N+" describes the industry-standard purity class of electronic-grade polysilicon — the category Phase D targets with a technology partner. It is not a claimed specification of Syria Silicon material today. All product-grade outcomes remain subject to metallurgical confirmation.

5. How an anchor partner enters

- Fund Phase A (USD 105M staged, gated) and secure preferential rights across the city — the lowest-risk anchor position.
- Fund the enabling studies (power options, JORC, metallurgical test work, glass-sector JV scoping): small capital, controls the critical path.
- Phase-specific entry: glass and building materials (Phase B) offers the earliest industrial revenue at the lowest technology risk; smelter and polysilicon (C–D) suit metals and energy groups; cells and modules (E) suit established PV manufacturers seeking regional capacity.
- Integrated city partnership: a consortium structure across phases, with the power IPP carved out to an energy partner.

6. What Syria Silicon brings

The resource and its assay record; the government framework (operating MoU on the basis of mining approval, direct working relationships in Damascus); the in-country operating company (Nawras Alali Silica & Minerals LLC); the logistics corridor to Tartus; the Phase A execution plan and validated financial model; and a founding team spanning Syrian, Australian and international experience. The partner proposes the structure; the company's evaluation criteria are speed to production, execution capacity, offtake strength, technical credibility, compliance viability, and long-term alignment.

7. Disclaimer

This document has been prepared by Syria Silicon for evaluation purposes under confidentiality. It does not constitute an offer to sell or a solicitation to purchase any securities. Estimates and projections reflect stated assumptions and pending confirmations, and actual outcomes may differ materially. Recipients should conduct independent due diligence. Phases B–E figures are AACE Class 5 ranges expected to change materially through feasibility.
